

ZOOMING IN ON THE CORONAL POLES WITH SOLAR ORBITER

DAVID BERGHMANS¹, DAN SEATON^{2,3}, MATTHEW WEST¹ ON BEHALF OF THE EUI TEAM
POLAR PERSPECTIVES MEETING, HAO, BOULDER, COLORADO SEPTEMBER 2018

¹ROYAL OBSERVATORY OF BELGIUM, BRUSSELS, BELGIUM

²CIRES, UNIV. OF COLORADO, BOULDER, COLORADO, USA

³NOAA NATIONAL CENTERS FOR ENVIRONMENTAL INFO., BOULDER, COLORADO, USA

SOLAR ORBITER OVERVIEW

- Mission 2020–2030
- 10 instruments
- Both in-situ & remote sensing

INSTRUMENTATION

In Situ

- EPD: Energetic Particle Detector
- MAG: Magnetometer
- RPW: Radio and Plasma Waves
- SWA: Solar Wind Analyzer

Remote Sensing

- EUV: Extreme Ultraviolet Imager
- METIS: Coronagraph
- PHI: Polarimetric and Helioseismic Imager
- SoloHI: Heliospheric Imager
- SPICE: Spectral Imaging of the Coronal Environment
- STIX: X-ray Spectrometer/Telescope

Solar Orbiter has shipped for its pre-flight test campaign in Germany as of this week.

METIS CORONAGRAPH & POLARIMETRIC AND HELIOSEISMIC IMAGER

- PHI provides full-disk and high res (up to 150 km) vector magnetic field and LOS velocity maps
- METIS observes the WL corona between 1.6 and 3.0 R_{Sun} at closest approach

QUESTIONS FOR A NEW VIEW

- Are polar coronal holes different from low-latitude coronal holes? How and why?
- Polar coronal holes don't experience differential rotation, the environment is much more static and PCH's are largely stable for much of the solar cycle. What does that mean for their evolution?

01 Jul 1996 - $I_{\text{pol}}/I_{\text{eq}}=0.85$

01 Jul 2000 - $I_{\text{pol}}/I_{\text{eq}}=0.73$

01 Jul 1997 - $I_{\text{pol}}/I_{\text{eq}}=0.83$

01 Jul 2001 - $I_{\text{pol}}/I_{\text{eq}}=0.80$

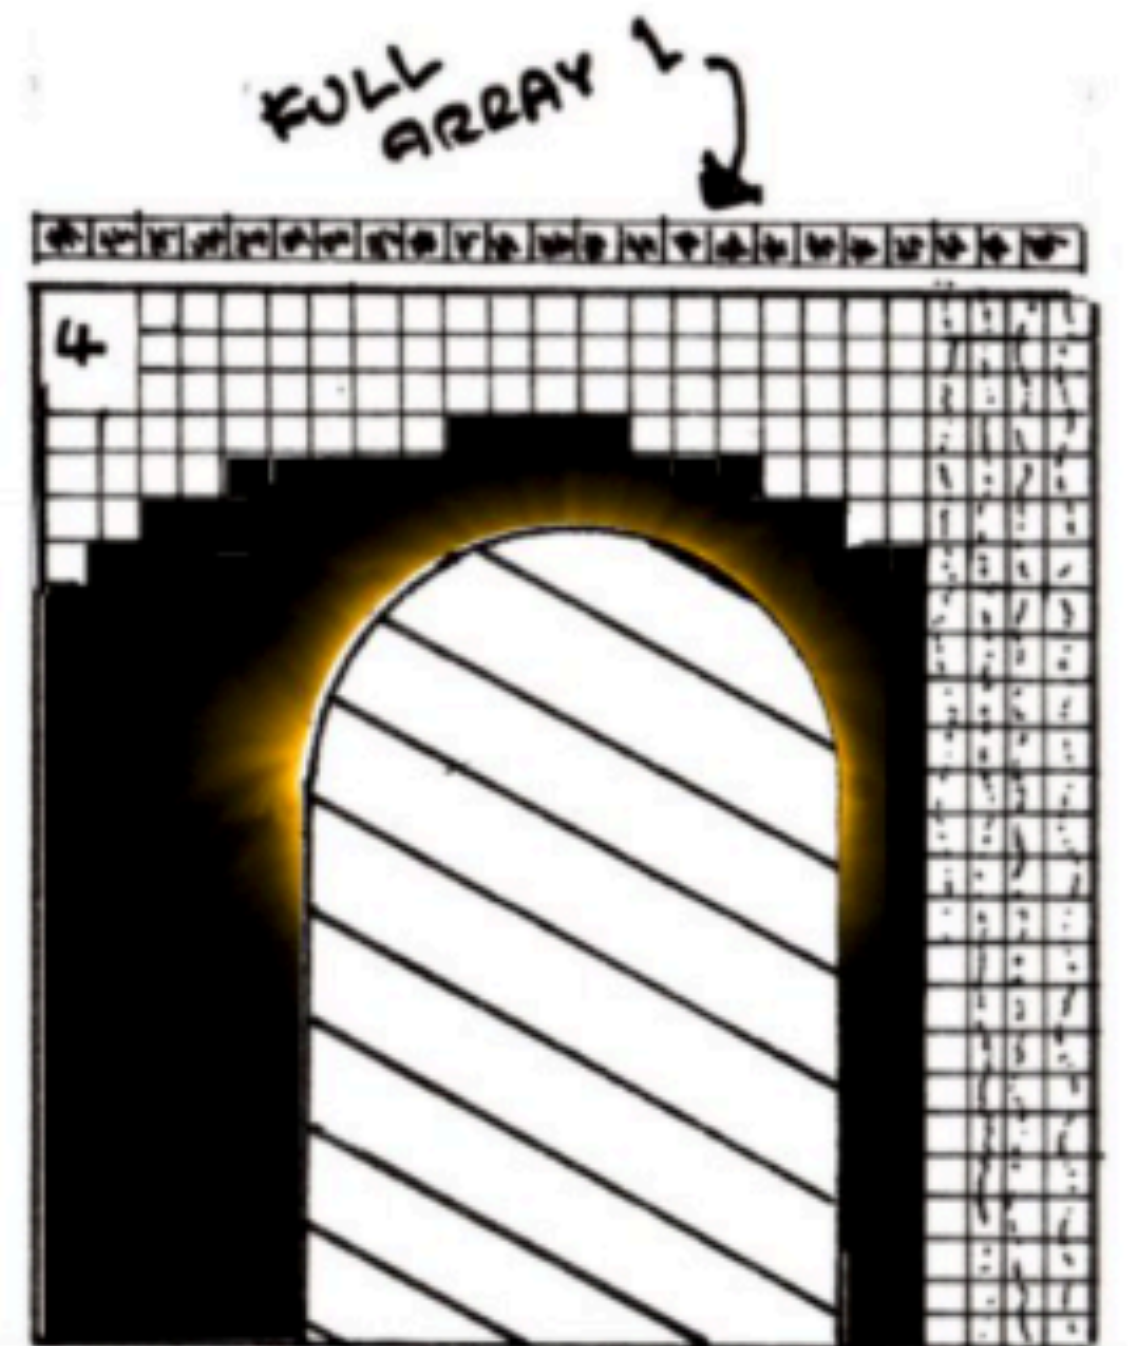

WE START BY TAKING
AN IMAGE OF THE SUN
AT TIME $T=1$

WE REMOVE THE SOLAR
DISK, AND THE SIGNAL
BELOW

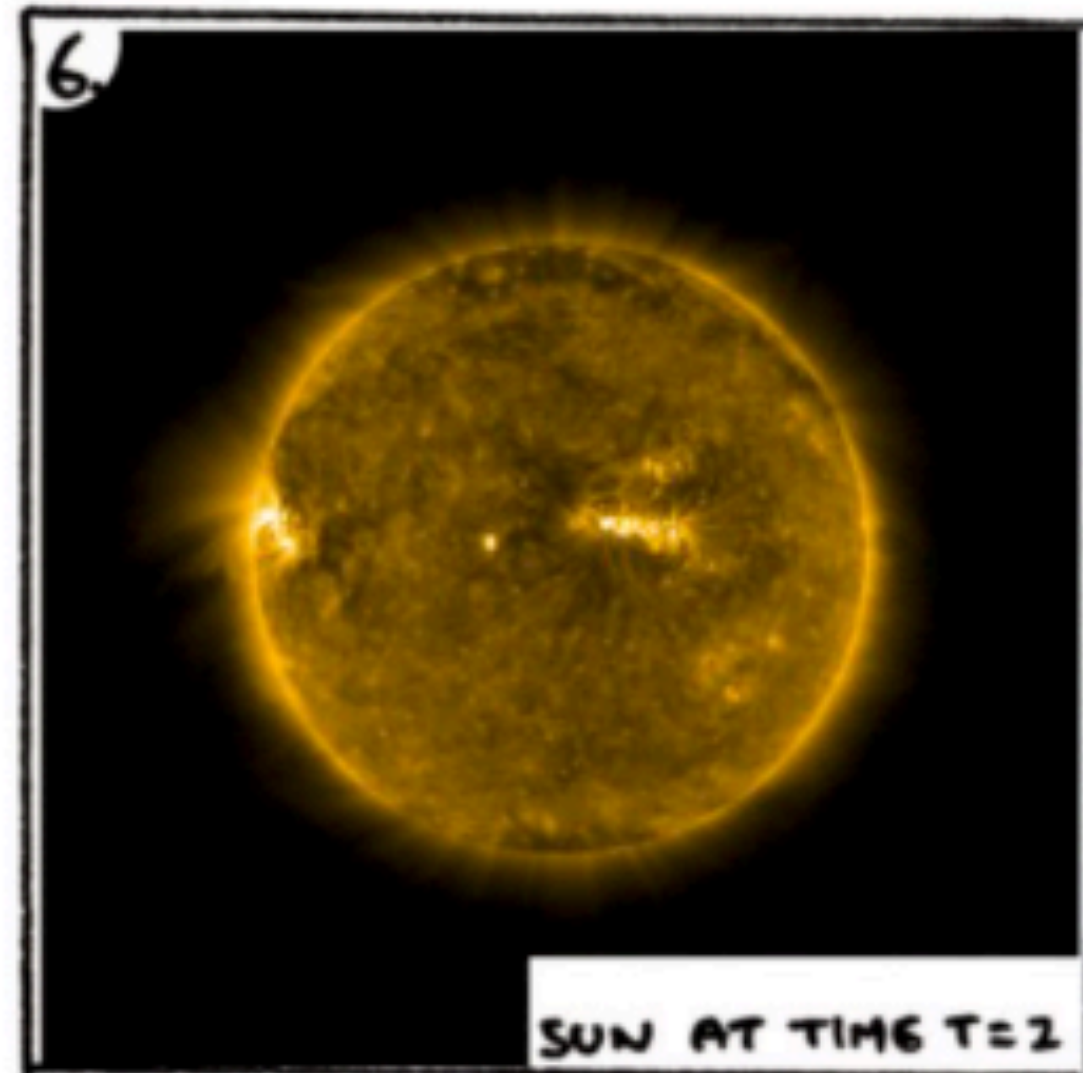

NEXT READ EACH 'COLUMN'
OF PIXELS IN THE IMAGE,
SUM THEM, AND READ INTO
AN ARRAY.

WE THEN PUT ARRAY 1 IN THE MIDDLE OF A NEW IMAGE

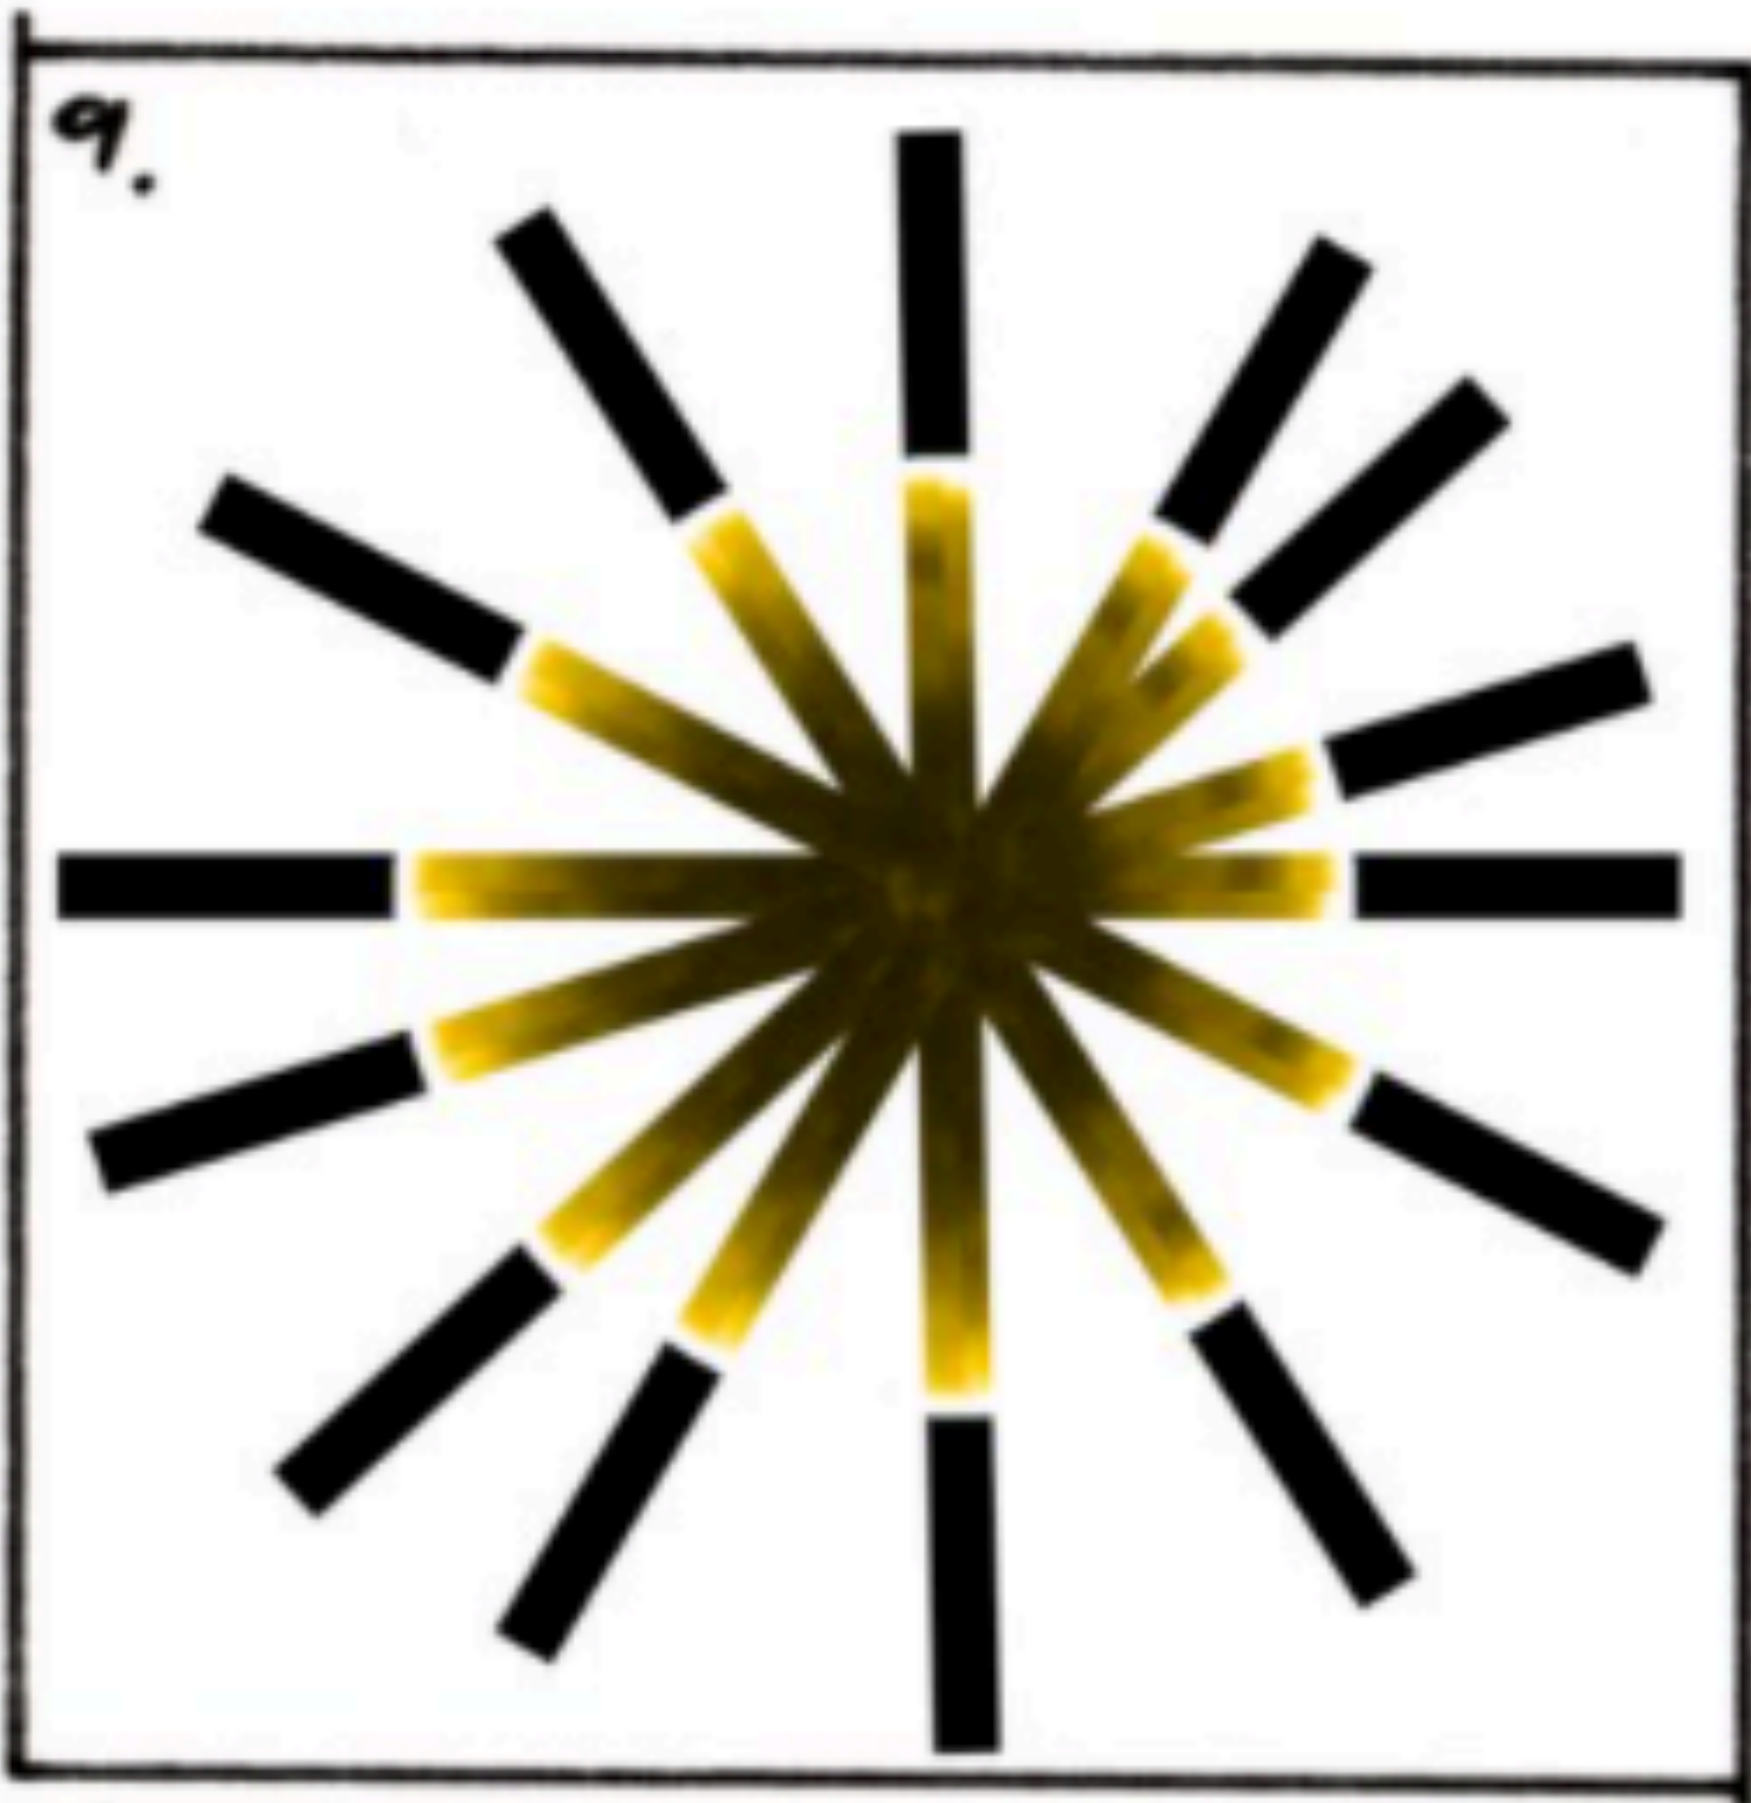

WE REPEAT STEPS 1. TO 4. USING AN IMAGE AT A SLIGHTLY LATER TIME, T=2, CREATING ARRAY 2.

IN THE TIME BETWEEN T=1 AND T=2 THE SUN WILL HAVE ROTATED BY ANGLE θ . WE COMBINE ARRAY 1 AND 2 USING THE ANGLE OF ROTATION θ .

WE REPEAT STEPS 1 TO 4 UNTIL WE HAVE ENOUGH IMAGES TO COVER $\frac{1}{2}$ A CARRINGTON ROTATION ($\frac{1}{2}$ A SOLAR ROTATION).

THIS IS DONE AT A FAR
FINER SCALE IN REALITY
CREATING A POLAR IMAGE
WITH SOME CLEVER
SCALING AND INTERPOLATION

IF DONE QUICKLY THE IMAGE
WOULD BE SEEMLESS. BUT
WE SEE SOME CHANGES
OVER THE CARRINGTON
ROTATION.

June 2018 – September 2018

SOLAR ORBITER MISSION PLANNING

- **Operations must be planned far in advance (>6 months)**
- Solar Orbiter Operation Plans (SOOPs)
 - Other instruments can join and plan accordingly, but SO can't alter advance planning, so early science suggestions are welcome
- Remote Sensing: 10 day perihelion passes, 10 days high latitude (N/S), so 30 days per orbit with remote sensing
- In Situ: available all the time

DATA AVAILABILITY

- **Limited Telemetry:** $\approx 16,000$ images per orbit, $\approx 320,000$ mission lifetime
- Open data policy
- Low Latency data arrives within days (comparable to STEREO Beacon Data)
 - Used for identifying important/disposable data
 - Still in the planning stages
- Other data can be available in as long as six months – available to the community on arrival, no embargo

EUI SCIENCE LEADS

- **Pierre Rochus (PI, Belgium)**
- David Berghmans (Co-PI, Belgium)
- Louise Harra (UK)
- Udo Schühle (Germany)
- Frederic Auchère (France)
- Werner Schmutz (Switzerland, Emeritus)
